ABSTRACT

Although academic employment of full-time scientists and engineers increased by three percent in 1977, more than one-fourth of public and private institutions reported a reduction in employment levels. There appeared to be a shift in emphasis toward applied rather than basic research. The employment of women as full-time scientists and engineers in the academic sector has grown at a rate approximately double that of men in 1977. Among the other information contained in this report is a chart of the number of scientists and engineers employed by the fifty leading situations broken down by field and sex. (BB)

SCIENCE RESOURCES STUDIES

NATIONAL SCIENCE FOUNDATION ● WASHINGTON, D. C. 20550 ● FEBRUARY 15, 1978 ● NSF 77-327

Academic Employment of Full-Time Scientists and Engineers Increased Another 3 Percent in 1977

Of the 2,190 institutions included in NSF's 1977 Survey of Scientific and Engineering Personnel Employed at Universities and Colleges, 1,835, or 84 percent, responded; NSF provided estimates for the remaining 355 nonrespondents. Among the 302 doctorate-granting institutions surveyed—which accounted for more than two-thirds of total employment of academic scientists and engineers—the response rate was 96 percent. Because of the excellent rate of response from these larger institutions, the rate of estimation made by NSF for the total number of scientists and engineers amounted to only 11 percent in 1977. However, since totals also include additional estimates by some of the institutions, small yearly changes should be viewed with caution ...

- Despite continuing financial pressures at manyinstitutions of higher education, the budgetary constraints of recent years have not been so severe as to prevent the addition of professional staff in science and engineering(S/E) fields. Employment of full-time scientists and engineers at universities and colleges, which account for approximately one of every eight scientists and engineers in the United States,³ rose by 3 percent from January 1976 to January 1977, to 236,200, continuing the average growth of 3 percent reported annually since 1969. The slow steady growth in employment of scientists and engineers at academic institutions may be attributed to a combination of factors, such as: (1) The recent upward trend in graduate enrollment in \$/E fields; (2) real, though small, growth in academic R&D expenditures, due largely to increased Federal support; (3) an increase in institutional control of personnel costs (through more restrictive tenure-granting policies and by hiring of a larger percentage of slower-ranked instructional staff); (4) a possibility that employment in S/E fields is increasing at the expense of non-5/E fields; and (5) deferral of some nonpersonnel-related expenditures in periods of budget cutbacks.
- The 1976-77 employment gain was not shared by all institutions. More than one-fourth of both public and private institutions reported reduction in their employment levels.

- As a result of the present pattern of academic research support, R&D scientists and engineers are shifting their research emphasis toward "applied" areas of current interest and away from long-term or traditionally "basic" lines of research. Applied research and development has increased from a 23- percent share of total academic R&D expenditures in fiscal year 1970 to a 32-percent share in 1976.2 A shift in the focus of Federal academic R&D support has been the principal reason for the increase in the proportion of applied R&D activities at universities and colleges.
- The number of full-time scientists and engineers within public institutions has risen by 4 percent on an average annual basis between 1969 and 1976; the growth rate dropped to 3 percent between 1976 and 1977. Employment within the private universities and colleges, however, has increased by only 1 percent annually over the same period, despite a 2-percent increase in each of the last 2 years.
- The employment of women as full-time scientists: and engineers in the academic sector has grown at a rate approximately double that of men between 1976 and 1977.

Trends in Full-Time Employment

The total number of full-time scientists and engineers at all universities and colleges rose by nearly 3 percent from January 1976 to January 1977 to 236,200. This was the eighth consecutive increase since 1965 when this survey series began, despite claims of financial problems by officials of many institutions of higher education and by various higher education analysts (table 1). The 3-percent average annual growth in employment of full-time scientists and engineers at academic institutions from 1969 to 1977 agreed closely with the 4-percent annual growth in total higher education enrollment and the 3-percent annual growth in total graduate enrollment in the sciences and engineering from 1971 to 1976.

While budget constraints, fluctuations in student enrollment, significant inflation, and reduced value of endowments all have had an adverse impact on academic science programs at many institutions of higher education. It the majority of institutions have thus far managed

Description of programme transport

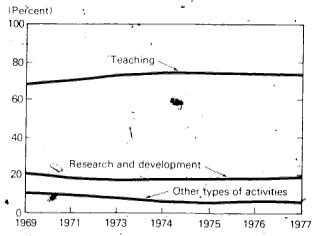

to continue to operate without reducing employment of scientists and engifteers. If these economic pressures continue, academic institutions may soon need to address questions involving possible reductions in their overall employment levels, and thus, also of scientists and engineers, and reallocation of financial and personnel resources between teaching and research functions. Other issues that are being addressed are associated with the aging of faculty and severe limitations in the number of positions available to young investigators.

Type of Activity

Approximately three-fourths of full-time scientists and engineers employed at universities and colleges in January 1977 were reported as primarily engaged in teaching, a ratio that has remained nearly constant over the past 3 years (chart 1). The shifting emphasis from research into teaching over the previous decade, thus, has apparently halted. In addition, the composition of research activity between basic and applied lines of inquiry, as well as the level of research funding at academic institutions, may be largely dependent upon the perceived needs and interests of Federal agencies.

During the seventies employment of full-time R&D scientists and engineers has grown at a rate comparable to that of R&D expenditures (in constant dollars) at academic institutions. Employment of full-time R&D scientists and engineers grew at an average annual rate of 2.1 percent from 1969 to 1977, compared to an average annual increase of 1.4 percent in academic R&D expenditures for approximately-the same fiscal years, 1970-76. The difference in growth patterns may be explained, in part, by the labor-intensive nature of

academic R&D costs. Nonpersonnel-related spending, since it can be postponed in a period of economic constraints, is more dependent upon short-run financial trends than is employment. There is less flexibility for deferral of labor-intensive costs because of the fixed nature of salaries for both tenured faculty and for full-time support staff.

Field of Employment

Each of the major areas of employment showed increases in S/E employment from 1976 to 1977, ranging from less than one-half of 1 percent for social scientists to nearly 9 percent for environmental scientists (table 2).

Institutional Control

Between 1969 and 1977, publically controlled institutions have increased their employment of full-time scientists and engineers by 4 percent on an average annual basis. They employed 70 percent of all full-time personnel in 1977, up from 64 percent in 1969. Private institutions retained virtually the same employment level between 1969 and 1975; however, it is encouraging that in the 1975-77 period, employment rose by 2 percent per year, an indication that the financial plight of private institutions may not be as severe in precent years as originally thought (chart 2).

Level of Institution

Doctorate- and master's-granting institutions together increased their number of full-time scientists and engineers by nearly 4 percent to a total of 186,800, while all undergraduate institutions showed a decline of less than 1 percent to 49,400. Graduate institutions accounted for 79 percent of all full-timers in 1977, a proportion that has remained relatively steady over the past 12 years of the survey's history. However, over one-fourth of all

SOURCE: National Science Foundation

institutions showed declines in their employment levels from 1976 to 1977. The largest proportion of institutions with employment declines (37 percent) occurred at the master's-granting level, while 2-year institutions showed the smallest relative number of reductions (23 percent). Although a substantially higher share of the master's-granting institutions reported reductions than 2-year institutions, the total number of full-time scientists and engineers employed at master's-granting institutions increased by 3 percent from 1976 to 1977, while employment at 2-year institutions remained at virtually the same level.

Sav

Women employed as full-time scientists and engineers continued to show larger relative increases (nearly 4 percent) than men (2 percent) between 1976 and 1977. Despite a growth rate approximately double that for men over the last 3 years, the overall proportion of women scientists and engineers has changed little since 1974—up from 15 percent to 16 percent of all full-time scientists and engineers employed at academic institutions. This minor growth is not surprising since, in view of the small starting base, rather large annual changes would be required to change the ratio significantly over a short period of time. Even if these same differential growth rates were to continue for the next 10 years, the proportion of academic women scientists and engineers would rise to only about 19 percent of the total. This has definite implications for the implementation of Federal policies seeking to correct the present imbalance in

5

employment opportunities for women scientists and engineers.

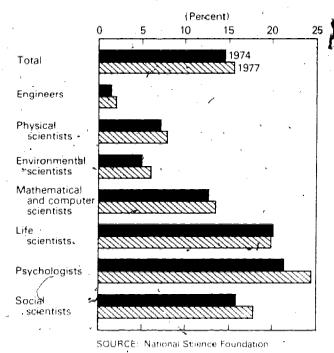

Women represent a considerably higher proportion of S/E employment in the academic sector than in the national employment scene; in 1974 they represented only 6 percent of all scientists and engineers in the United States.

Between 1974 and 1977 women showed relative gains in academic employment in all but one of the major science areas—the life sciences—where little change occurred. Psychology, which employed the highest proportion of women, showed an increase from 21 percent to 25 percent during this period, the largest relative gain of women in any field (chart 3).

Chart 3. Women as a percent of all full-time scientists and engineers employed at universities and colleges by field:

January 1974 and January 1977

The 56 Leading Institutions

The 50 leading institutions shown in table 3 employed 76,100 full-time scientists and engineers, or 32 percent of all full-timers at academic institutions. Across the major fields the concentration at these 50 institutions ranged from 18 percent for mathematical and computer scientists and psychologists to 44 percent for life scientists. The high proportion of life scientists is attributable to the fact that many of the 50 leading universities have affiliated medical schools or agricultural experiment stations.

There is considerable variation in the numbers and proportion of women employed among the 50 leading universities; a principal reason for this divergence is women employment levels is a difference in emphasis on career development outside the normal faculty ranks. Such a program may include sizable numbers of professional staff that have not attained graduate degrees. The University of Michigan for example, with 735 women representing 31 percent of the institutional total for full-time scientists and engineers, reported a relatively low proportion of doctorate-holders (59 percent, compared to 79 percent for all doctorategranting institutions) and a high number holding a bachelor's degree as their highest earned degree (25 percent, compared to 8 percent for all doctorate-level institutions). Many of these individuals at the University of Michigan are professional staff on "research career ladders" and generally are assigned to assist primary researchers.

Comprehensive statistical tabulations representing these survey results have recently been published to the report. Detailed Statistiscal Tables, Manpower Resources for Scientific Activities at Universities and Colleges, January 1977 (NSF 77-321), copies of which may be obtained free from the Division of Science Resources Studies. National Science Foundation, Washington, D.C. 20550.

A final report analyzing the data from the 1977 survey will not follow this Highlights. Full analytical reports and detailed statistical tables will be issued biennially in the future. For example, the next final report will contain January 1978 survey data and trends. Data tapes for January 1977 and prior surveys may be purchased from:
